Abstract — The institutional repository created in UNED (Universidad Nacional de Educación a Distancia, Spain) is a project that, originated from the computer services of the Library of the Institution, aims to provide coverage to members and academic staff at the University. The project, currently in full operation, offers a set of services for the management, preservation and access over the Internet of digital materials created by its members. Derived from these services, the purpose of the repository is the documentary management, preservation and access over the Internet of digital materials created by the University and its members. It is essentially an institutional commitment to control these digital materials [1]. Therefore, an institutional repository is a recognition of the increasingly intellectual activity represented in digital objects, so that the main responsibility of an institution is focused in exerting control means on their intellectual productions, making them accessible, easily retrievable and ensuring their existence through time. A great projection case in science and academic environment is the Massachusetts Institute of Technology (MIT) [2], where library collections are promoted, not only to conserve and maintain them but also to generate open courses, i.e., the interaction of different materials to focus and specialize certain specific lectures.

II. BACKGROUND TO THE INTRODUCTION OF THE SYSTEM

UNED (Universidad Nacional de Educación a Distancia) is a Spanish institution who operates all over the country, having delegations in every region. This special structure makes the University to produce and create digital contents and systems in a different way. The extension of agencies and staff at UNED inside the Spanish frontiers and through foreign countries delegations, given the national scope of its reach with the consequent dispersion of UNED students and professors, is not exactly a feature shared with other universities and institutions. This particular situation, with large numbers of registrations and collaborations, provoke the generation of a growing, complex and heterogeneous digital content. At first instance, the UNED library conducted an analysis approaching to digital content accessible through the virtual campus, and a huge number of locations on department websites were recognized. From the analysis two main evidences were extracted. First, it was recognized that free accessibility of contents was related to departmental personnel’s interest on its academic and research dissemination. These materials include journal articles, book chapters, papers presented at various conferences and seminars, etc. Even with such a great academic and educational value, this material had a low degree to be spread out through scientific publication.
traditional channels. The second conclusion came from this first evidence and was based on the need to standardize the location of these materials. That is, in such an scenario it’s essential to create a large core to access this documentation on a consolidated and linked way.

III. CHARACTERISTICS OF MANAGED DIGITAL OBJECTS IN A REPOSITORY

The main functional properties a digital object is characterized are the condition of heterogeneity and complexity. The first one consists on the definition of the objects diversity that a digital system can hold. This diversity is defined by MIME types and can be texts, images, films, sound recordings, tables, datasets, etc. Even an object sustained in a digital system can be composed by a set of any of them, which gives to the object the additional property of complexity.

Therefore, this second defined feature, complexity, suggests that when generating an object, it is composed of different parts. Therefore, it would be inaccurate to talk about documents when defining the component to integrate into a repository. As a reference example to a specific object, a doctoral thesis, the complexity lies in its composition, being constituted the subject as a pdf document, data tables, and even related graphics software, used to perform certain calculations.

Given the global situation of information and data worldwide, there’s an increasing need to make visible productions on the web. The way to make a production visible is to link a heterogeneous and complex object to a persistent URI at the time of its creation. Moreover, taking into account the growing importance of the Semantic Web, it is desirable to have defined every digital object in a semantic representation in the local repository context. This provision is indicative of the creation of a semantic link that allows each and every one of the objects in each repository.

IV. THE DESIGNING OF ESPACIO-UNED

The eSpacio -UNED institutional repository is based on Fedora [3], SOA architecture backend for digital content. Fedora has, therefore, defined a set of Web services published by WSDL, where customers can be connected, created by third parties. Consequently, Fedora is a generic management middleware, capable to contain any type of digital object, providing more services than just an application where the types of contents to be managed have to be adapted. This model set in place a number of architectural features, where the main ones are: definition of a new structure for digital objects that can be serialized in XML by means of transformations (fedora.xsd); ability to manage assets locally or remotely; establishment of relationships between digital objects and among the components of a digital object, expressed in RDF [4]: http://www.fedora.info/definitions/1/0/fedora-relsext-ontology.rdfs; access control using XACML standard with different levels of granularity [repository, object, components of an object (datastreams)]; authentication: login, sign on, LDAP and Shibboleth; control and maintenance of different versions of a digital object; audit and data curation. Consequently, Fedora is based on a concept of digital object container that maintains the data structure. Every digital object is, therefore, an aggregation of elements that can be used individually or as part of a set. As a result, both can be heterogeneous and complex, equipped with a component that accounts for relations between the various objects both inside and outside repository.

About the functionality of Fedora, free software with GPL license it is a noteworthy characteristic, leading to immediate benefits, such as suitability for academic environments to be more reliable, robust and secure; very low cost that allows locating financial resources in other areas that would greatly improve the public utility of the universities (infrastructure, scholarships, research support, etc.); and type of software that requires less computational resources and extends the life of computer equipment from both universities and students, avoiding rapid cycles of obsolescence and thereby, optimizing the investment.

V. HOW THE REPOSITORY IS INTEGRATED IN THE ARCHITECTURE OF THE UNIVERSITY

SOA architecture is used by UNED to offer its services to generate and implement specific application and modules. As a system integrated, the architecture of the repository is placed in a central situation on a general diagram of system and services. A diagram has been shown in Figure 1, which shows this scenario in the blocks located at the top, which highlights the portal eSpacio, management University site, the OCW open courseware site, Tele-UNED site and other specific webs from Faculties and Departments. The idea of integration is focused on FEDORA situation as a bottom layer with functions based on the provision of management services to these sites.

VI. SERVICES OFFERED BY ESPACIO-UNED

The services and DOs treatment and management by Fedora is made generically, relying on relational databases and ontologies databases.

The repository is able to interoperate with other systems, both inside the institution as well as external
systems (administrative systems, portals, other repositories) so that their contents are easily removable and reusable [5]. Therefore, the digital repository eSpacio-UNED works with open protocols and standards. It can potentially be integrated as a central element in the information management network of the institution, enabling it to compete and collaborate more effectively and efficiently. The standards and protocols provide protection against obsolescence and inaccessibility. They represent a safe way to store content for future rebuilding, because all of them are universally understood, documented and published. There are not associated any licensing and use and distribution cost. The use of open protocols is also a prerequisite to ensure interoperability and as a consequence, the exchange and transfer of information. In this sense, the digital repository of UNED is consistent with the OAI-PMH [6] which means that their contents can be incorporated into networks of similar collections around the world and can be searched by agents from the Internet, including Google, Google Scholar, or OAI services like OAIster.

Ultimately, the most important services provided by the institutional repository eSpacio-UNED are described as a complete management service of any type of digital objects (CRUD) derived from the exhibition site (WSDL) from a series of management APIs, a configurable search service for any metadata or text, a data provider service under OAI-PMH, a service for the preservation of digital assets with automated creation of metadata PREMIS [7], and a service of creating on-demand Web rendering subsets of content objects (eg, electronic journals, collections of old books, etc.).

VII. AN EXAMPLE OF LEARNING OBJECTS LOADING

The Department of Electrical, Electronics and Control Engineering (in Spanish, DIEEC) from the Industrial Engineering Technical School at UNED has recently made a number of projects based on the recovery, reuse and organization of digital objects [8]. Those objects have been generated in the teaching and scientific fields. The nature and the origin of these objects is diverse, having objects removed from lessons, practices, departmental records, and resolution exercises, exams, presentations by department members and documents from conferences in which the department is actively involved.

The amount of digital objects is high, so that they did reveal the need to unify all of them in the same context for reusing. The environment and services offered by the institutional repository perfectly fit to the objectives of DIEEC related to the dissemination and access to digital objects in the academic field. Once reusable digital objects are individually organized with a metadata additional structure, that defines every element, it has been proceeded to its incorporation into the repository. As a guide for the load of the digital objects, a description in the standard IEEE-LOM metadata of every one of them has been made. To access, they were stored in an open source database eXist XML (native) and a query is created through a single input file.

As Fedora schema objects are known, the creation of an XSLT transformation was made to begin a process of sequential reading of the file. The result was the incorporation of digital objects and their XML file descriptors in IEEE-LOM standard. The integration of the resulting objects has generated, in the environment of the repository, a number of elements making up the structure of every digital object. So, the components associated with the digital object are LOM metadata component, Dublin Core metadata component arising from the LOM description, component linked to the URL of asset, component of the relationship between the object to other related objects in the DIEEC and finally, FOXML representation.

The burden of these digital objects has been performed at various stages related to the different natures and origins of them. Thus, in a first stage related to the digital objects derived from the teaching of the department, the charge resulted in the incorporation of 1743 objects exploiting the import function to digital formats LOM, METS or ATOM. In a second phase, it has been proceeded to the incorporation of 5405 objects derived from the presentations and congressional work documents from the department.

Figure 2 shows a general aspect of the hierarchical structure "isMemberOf" in which objects and their components are organized, which are available from all elements of a learning object. In the right block, the arrangement of the components is shown, connected to a digital object, known as "power supply" which in turn belongs to the group known as "Analog Electronics" and that also, in turn is incorporated into all “DIEEC Learning Objects” represented to the left of Figure 4. As the component “Reference1” was redirecting the assets on the server, a FTP server from all of then was implemented in Apache server which supports eSpacio.

In conclusion, digital objects have been generated from a LOM description, available to be displayed on the Web, with persistent identifiers and all the features added due to its integration in the repository space, and search within that subset, that OAI-PMH protocol incorporates in specialized portals, accessible through Google, for export in XML files, etc.
VIII. A PARTICULAR VIEW OF THE WEB SITE INTERFACE

The institutional repository, eSpacio-UNED, provides access and offers its services through the web page address http://e-spacio.uned.es/. The homepage access of the repository has a functional aspect, as shown in Figure 3. At the same time, there are several areas in which it stresses the header consists of external links. It has left the means of desk research, either generally or specifically by author. It also allows through additional links, access to other types of searches including those advanced by multiple search fields.

![Image](image_url)

Figure 3 – User interface in eSpacio-UNED – Access homepage

Given the widespread use of UNED digital journals, they take a leading role with access through direct links to its own page, where everyone of them can be introduced, being possible the access to the published issues. An outstanding news and additional features in recent days can also be viewed. When a query is made, the answer is returned in the same dynamic environment, providing a list of matches to their criteria, as shown in Figure 4. Search terms are marked in yellow in the list box provides the information of the loading date of the document along with the author and the description of the digital object type. Two more fields shall also be included, which respectively provide the link to download the document and the value of the source or collection that the digital object belongs to.

Figure 4. Results page due a query.

The eSpacio-UNED repository website offers some added services such as the ability to view statistics associated with the most downloaded articles per month and year, the most popular authors, as well as general operating data repository on the quantity of available documents and items and countries of origin of the IP's from which they have consulted and downloaded.

IX. CONCLUSION

Throughout this paper, the features and characteristics of the institutional repository space-UNED have been outlined. The launch of the repository involves the creation of a common digital space in which productions created by its members are hosted. Due to the functionality of the repository based on the determination of collections that allows a rational classification of digital objects, they can be reused as learning objects. The repository offers a range of services designed to develop a coherent and coordinated approach for the capture, identification, storage and retrieval of digital contents. By means of systems integration, an environment is created to offer a managed treatment of contents, increasing opportunities for more effective use of the results of the activity of the institution and encouraging collaboration across disciplines and units.

From the standpoint of an author, he can find a centralized and assisted place to locate his work. Each of them have a persistent URI associated, which enables it to be visible on the Internet and therefore, be found by search agents and users, leading to increased screening and dissemination of its work. In short, the repository eSpacio-UNED aims to stimulate innovation, facilitate a qualitative analysis of the work of its members, sustain the work of teaching and learning, serve as a system for recording ideas and offer a catalogue of intellectual heritage of the institution.

ACKNOWLEDGMENT

The authors acknowledge the Spanish Science and Innovation Ministry and the CYTED-508AC0341 “SOLITE – FREE SOFTWARE IN TELEFORMATION” Project, as well as the support of the Complimentary Action TSI2007-31091-E “Objetos educativos reutilizables (para el EEES en las tecnologías de la información y las comunicaciones)”.

In memoriam of Tomas Pollan a good friend and a best colleague.
